# Hurdles in Renewable Integrations – Some Practical Considerations

Steven Wang, Quanta Technology  
Henry Chao, Quanta Technology  
Francis Wang, NextEra Energy Resources

October 19, 2021

# Introduction

- Current situation:
  - Rapid introduction of renewable technologies to meet public policy requirements
- Two potential outcomes:
  - Wholesale market energy prices will be lower, challenging economic viability of fossil generation to stay in operations;
  - Renewable projects are subject to high production curtailment
- What do we need:
  - Systematical review of the current analytical practices, grid modeling, data collection method and categorization
  - A complete picture of where the energy deliverability bottlenecks are and what are the cost-effective mitigation solutions
- Our methodology: Production Cost Simulation

## Production Cost Simulation

- Perform Security Constrained Economic Dispatch (SCED) simulations for a whole year (8760-hour), to assess the impact of current and future transmission congestion on Locational Marginal Prices (LMPs)

$$\begin{aligned}
 & \text{Min } \left\{ \sum \bar{c}_g \bar{G} + \sum \bar{c}_d \bar{D} + \sum \bar{c}_\theta \bar{\theta} + \sum \bar{c}_t \bar{T} \right\} \\
 & \text{s.t. } \quad \sum \bar{G} = \sum \bar{L} \quad \text{(Real Power Balance)} \\
 & \quad \bar{G}^{\text{Min}} \leq \bar{G} \leq \bar{G}^{\text{Max}} \quad \text{(Real Power Gen. Limits)} \\
 & \quad \bar{D}^{\text{Min}} \leq \bar{D} \leq \bar{D}^{\text{Max}} \quad \text{(Dispatchable Demands)} \\
 & \quad \bar{\theta}^{\text{Min}} \leq \bar{\theta} \leq \bar{\theta}^{\text{Max}} \quad \text{(Phase Shifter Limits)} \\
 & \quad |\bar{T}| \leq \bar{T}^{\text{Limits}} \quad \text{(Transmission Constraints)}
 \end{aligned}$$

**Control Variables**

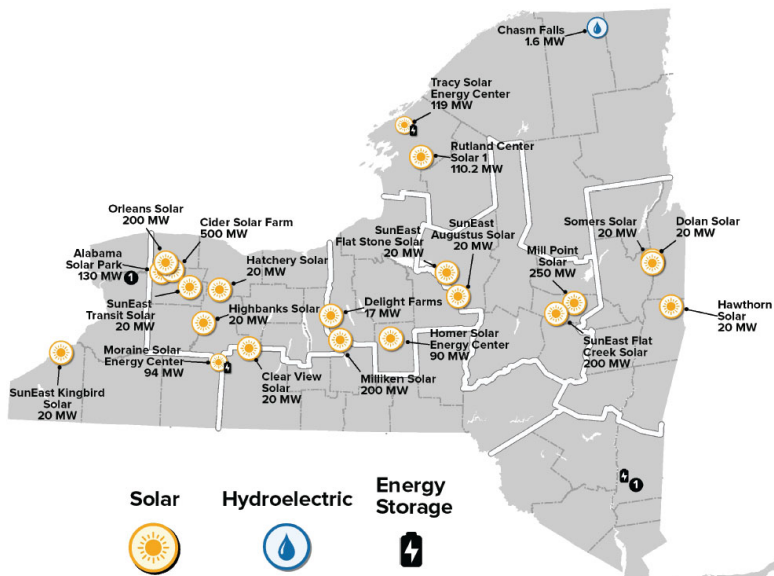

# Hurdle 1: Grid Deliverability Capability

- Example: New York state

- The Climate Leadership and Community Protection Act (CLCPA) mandates that New York consumers be served by 70% renewable energy by 2030 (“70x30”)

Year	Gross Load (GWhs)	Renewable Energy (GWhs)	Renewable Energy (%)
2019	155,848	37,294	24
2030	162,378	113,665	70

- Production cost simulation considering renewable projects that passed NYISO Class Year reports or contracted under NYSERDA Tier 1 REC or RPS

NYSERDA REC Projects	MW Capacity	2025 curtailment	2030 curtailment
Project 1	100.0	2.4%	6.5%
Project 2	50.0	0.7%	12.1%
Project 3	90.0	9.1%	13.2%
Project 4	50.0	0.0%	0.0%
Project 5	180.0	0.7%	0.1%
Project 7	80.0	0.0%	0.9%
Project 8	280.0	0.0%	0.0%
Project 9	200.0	0.0%	0.4%

## Hurdle 1: Grid Deliverability Capability (Cont'd)

- Key takeaways:
  - Federal and state agencies need to coordinate to ensure the later-procured renewable projects will not cause production curtailments to the renewable projects, existing or previously procured/contracted.
  - The separation of byway (e.g., 115 kV and below) and highways (e.g., 230 kV and above) transmission projects can result in ineffective transmission expansion.

Slide 5

## Hurdle 2: Grid Flexibility in Operation

- The hourly variable renewable penetration (VRE) of renewable resources can reach over 100% of the demand in the future
- Reaching the 70x30 CLCPA goal will require both the existing resources and the development of newer, dispatchable, carbon-free technologies to mitigate the risk to ratepayers

NEW YORK YEARLY RENEWABLE PENETRATION VS LOAD IN 2030

HIGHEST VRE PRODUCTION/LOAD RATIO IN 2020 AND 2030

## Hurdle 2: Grid Flexibility in Operation (Cont'd)

- Changes in operations will be required with the large-scale installation of generation
- Grid operators would need more dispatchable and long-duration energy resources to manage the substantially different systems to maintain reliability in 2030

Max VRE Penetration Limit %	Renewable Curtailment %	Renewable Curtailment after 4.4GW Storage
100%	5.1%	1.6%
90%	7.9%	2.7%
80%	11.7%	4.3%
70%	16.8%	6.8%
60%	23.4%	10.3%

## Hurdle 3: Grid Operation and Resilience

- Resource adequacy: Additional resource requirements to address resource adequacy alone will rise from 350 MW to 2,650 MW in 2030 for New York City area.
- In 2030, the sustained power ramps will reach 30 GW over a period from 8am to 6pm and will experience a maximum hourly ramp of 13 GW midday.
- Also, the reduction in short circuit currents driven by the prevalence of inverter-based resources (IBRs) will have two serious risks:
  - a. Short circuit ratio (SCR) limits and the ability of the NY grid to integrate the required MWs of IBRs without destabilizing the inverter controls,
  - b. The ability of the protection system to detect faults.

## Conclusion

- Major hurdles for the proliferation of renewable integration:
  1. The limitation of grid delivery capability;
  2. The impact on grid flexibility under changing resource mix
  3. Demand and supply balancing in seasonal and real time grid operations
- Practical approaches to achieve optimal siting and interconnection of renewable projects:
  - Detailed common grid models are necessary for grid and market participants to increase overall renewable utilization and effective integration.
  - Regular and transparent planning studies based on the common models provide the critical information for the renewable development and renewable energy procurement
